

COVID-19 CADTH HEALTH TECHNOLOGY REVIEW

# Systemic Corticosteroids for the Management of COVID-19: A Review of Clinical Effectiveness

**This report was published on October 19, 2020.**

To produce this report, CADTH used a modified approach to the selection, appraisal, and synthesis of the evidence to meet decision-making needs during the COVID-19 pandemic. Care has been taken to ensure the information is accurate and complete, but it should be noted that international scientific evidence about COVID-19 is changing and growing rapidly.

Version: 1.0  
Publication Date: October 2020  
Report Length: 41 Pages

## Context and Policy Issues

The coronavirus disease identified in 2019 (COVID-19) is an infection of the respiratory tract caused by the Severe Acute Respiratory Syndrome-related Coronavirus 2 (SARS-CoV-2).<sup>1,2</sup> Since the World Health Organization (WHO) declared COVID-19 as a pandemic in March, 2020,<sup>3</sup> the disease has spread globally and is one of the major public health concerns in recent history. As of October 5, 2020 there were 35,274,993 cases of COVID-19 confirmed globally, and 1,038,534 confirmed deaths attributed to COVID-19.<sup>4</sup> In Canada, there were 173,123 cases and 9,541 deaths as of October 8, 2020.<sup>5</sup> Among those who develop COVID-19, most people have few- to no symptoms of the disease.<sup>1,6</sup>

Approximately fourteen percent of people identified as having COVID-19 require hospitalization and five percent are admitted to an intensive care unit (ICU).<sup>1</sup>

Clinical trials are currently underway to identify treatment options for COVID-19.<sup>7-9</sup> Current management strategies include symptomatic care, oxygen support (nasal cannula, invasive and non-invasive mechanical ventilation) along with experimental use of antivirals, empirical antibiotics, intravenous immunoglobulins, convalescent plasma, corticosteroids, and other drugs.<sup>1,6</sup> Preliminary results from a randomized trial in the UK (RECOVERY trial), published in July 2020, showed that the use of dexamethasone resulted in lower mortality among patients with severe illness receiving either invasive mechanical ventilation or oxygen alone but not among those receiving no respiratory support.<sup>10</sup> On September 2, 2020 WHO published an interim clinical practice guideline on the use of corticosteroids for COVID-19 based on prospective meta-analysis data from ongoing randomized clinical trials.<sup>7</sup> WHO issued a strong recommendation (based on moderate certainty evidence) for the use of corticosteroids versus no corticosteroids for the treatment of patients with severe and critical COVID-19. They also suggest not to use corticosteroids for the treatment of patients with non-severe COVID-19 (conditional recommendation, low certainty evidence).<sup>1,7</sup>

The objective of this report is to summarize the evidence regarding the clinical effectiveness of systemic corticosteroids for the management of COVID-19.

## Research Question

What is the clinical effectiveness of systemic corticosteroids for the management of individuals with coronavirus disease (COVID-19)?

## Key Findings

Five systematic reviews and four RCT were identified regarding the clinical effectiveness of systemic corticosteroids for the management of individuals with COVID-19. The evidence was of limited quality, and findings were inconclusive regarding the effectiveness of systemic corticosteroids with respect to mortality, patient symptoms, or medical care outcomes in patients with COVID-19. Adverse events were not assessed in six of the included studies (three primary studies, three systematic reviews); in the three studies that did quantify adverse events (one primary, two systematic reviews), no differences between treatment groups were identified.

## Methods

### Literature Search Methods

A limited literature search was conducted by an information specialist on key resources including MEDLINE, Embase, PubMed, the Cochrane Library, the University of York Centre for Reviews and Dissemination (CRD) databases, the websites of Canadian and major international health technology agencies, as well as a focused internet search. The search strategy was comprised of both controlled vocabulary, such as the National Library of Medicine's MeSH (Medical Subject Headings), and keywords. The main search concepts were systemic steroids and COVID-19. No filters were applied to limit retrieval by study type. Where possible, retrieval was limited to the human population. The search was also limited to English language documents published between January 1, 2018 and September 17, 2020.

## Selection Criteria and Methods

One reviewer screened citations and selected studies. In the first level of screening, titles and abstracts were reviewed and potentially relevant articles were retrieved and assessed for inclusion. The final selection of full-text articles was based on the inclusion criteria presented in Table 1.

**Table 1: Selection Criteria**

<b>Population</b>	Individuals with confirmed or suspected COVID-19
<b>Intervention</b>	Intravenous or oral systemic corticosteroids (e.g., hydrocortisone, dexamethasone, prednisone, methylprednisolone) alone or in combination with other therapies
<b>Comparators</b>	No treatment; placebo; standard care; other active treatments (e.g., remdesivir)
<b>Outcomes</b>	Clinical effectiveness (e.g., mortality, length of hospital stay, severity of clinical symptoms, viral load, safety [e.g., adverse events])
<b>Study Designs</b>	Health technology assessments, systematic reviews, randomized controlled trials

## Exclusion Criteria

Articles were excluded if they did not meet the selection criteria outlined in Table 1, they were duplicate publications, or were published prior to 2018.

## Critical Appraisal of Individual Studies

The included systematic reviews were critically appraised by one reviewer using A MeaSurement Tool to Assess systematic Reviews (AMSTAR 2),<sup>11</sup> and randomized studies were critically appraised using Downs and Black checklist.<sup>12</sup> Summary scores were not calculated for the included studies; rather, a review of the strengths and limitations of each included study were described narratively.

## Summary of Evidence

### Quantity of Research Available

A total of 541 citations were identified in the literature search. Following screening of titles and abstracts, 515 citations were excluded and 26 potentially relevant reports from the electronic search were retrieved for full-text review. Two potentially relevant publications were retrieved from the grey literature search for full-text review. Of these potentially relevant articles, 19 publications were excluded for various reasons. One prospective meta-analysis<sup>13</sup> was excluded because it included interim unpublished data from ongoing trials. Nine publications met the inclusion criteria and were included in this report. These comprised five systematic reviews (SR)<sup>14-18</sup> and four randomized controlled trials (RCTs).<sup>19-22</sup> Appendix 1: Selection of Included Studies presents a flowchart of the study selection. Additional references of potential interest are provided in Appendix 6.

### Summary of Study Characteristics

Three<sup>14,17,18</sup> of the five SRs had broader inclusion criteria than the present review, as they included studies in patients with severe acute respiratory syndrome (SARS) and middle east respiratory syndrome (MERS) in addition to those with COVID-19. Only the characteristics and results of the subset of relevant studies are described in this report.

Additional details regarding the characteristics of included publications are provided in Appendix 2.

### *Study Design*

Five SRs<sup>14-18</sup> – four with meta-analysis<sup>14,15,17,18</sup> – that were published in 2020 were included in this report. All SR authors searched for and included primary RCTs and observational studies. Authors of all included SRs searched multiple electronic databases to identify eligible primary studies. Three SRs<sup>14,15,18</sup> included preprints and meta-analyses in addition to peer-reviewed published studies. Lu et al.<sup>14</sup> searched for eligible publications from January 1, 2003 to March 31, 2020. The SR included 23 studies, among which, five were relevant to the current report. Sarkar and colleagues<sup>15</sup> conducted their search from January 1 to August 19, 2020. The SR included 15 RCTs and cohort studies. Veronese et al.<sup>16</sup> searched for studies from database inception to March 15, 2020 and identified four primary studies. Ye and colleagues<sup>18</sup> conducted a literature search from database inception to April 25, 2020 and included 35 primary studies, among which six were relevant to the current report. Lastly, Yang et al.<sup>17</sup> searched for retrospective observational studies from January 1, 2002 to March 15, 2020 and included no primary studies relevant to the current report.

The four primary clinical studies included in this report were RCTs.<sup>19-22</sup> The CAPE-COVID trial conducted by Dequin et al.<sup>19</sup> was a multicenter, double-blind, sequential trial conducted from March 7, 2020 to June 7, 2020. The Metcovid study by Jeronimo et al.<sup>20</sup> was a parallel, double-blind, Phase IIb clinical trial conducted from April 18 to June 16, 2020. The third RCT, the CoDEX trial by Tomazini et al.,<sup>21</sup> was an open-label trial conducted from April 17 to June 23, 2020. Lastly, the REMAP-CAP trial<sup>22</sup> is an ongoing multi-factorial (evaluates several treatment options simultaneously), open-label trial, embedded in routine care for pneumonia, that uses an adaptive platform whereby the intervention(s) evolve over time (e.g., in the event of pandemics or as new information is learned from interim analysis). . Patients were enrolled to examine the domain of relevance to this report (i.e., the corticosteroid domain) from March to June 2020. The characteristics and results of the corticosteroid domain are summarized in the current report.

### *Country of Origin*

The included SRs were conducted by authors from Canada,<sup>18</sup> China,<sup>14,17</sup> India,<sup>15</sup> and Italy.<sup>16</sup>

The REMAP-CAP<sup>22</sup> RCT was conducted at multiple sites across several countries, namely Australia, Canada, France, Ireland, the Netherlands, New Zealand, UK, and US. The other RCTs were conducted in Brazil<sup>20,21</sup> and France.<sup>19</sup>

### *Patient Population*

The population of interest for the included SRs was patients with COVID-19.<sup>14-18</sup> The number of participants from the relevant primary studies ranged from 542<sup>16</sup> to 15,754.<sup>15</sup> The mean age of study participants ranged from 48.7 to 56.3 years in one SR<sup>14</sup> and was 52 years in another;<sup>16</sup> less than half of participants in these SRs were women. Two other included SRs<sup>15,18</sup> did not report the mean age or the sex distribution of the population sample.

The CAPE-COVID<sup>19</sup> trial enrolled adult patients with confirmed or suspected COVID-19 who were admitted to the ICU. Patients also needed to fulfill at least one of the following four disease severity criteria to be considered eligible for the trial: 1) mechanical ventilation with a positive end-expiratory pressure of 5 cm H<sub>2</sub>O or more; 2) ratio of partial pressure of

oxygen ( $\text{PaO}_2$ ) to fraction of inspired oxygen ( $\text{FiO}_2$ )  $< 300$  on high-flow oxygen therapy, with an  $\text{FiO}_2$  of  $\geq 50\%$ ; 3) supplemental oxygen with a  $\text{PaO}_2:\text{FiO}_2$  ratio  $< 200$  (estimated using prespecified charts; or 4) pulmonary severity index  $> 130$ . Patients with septic shock (treated by vasopressors), hypersensitivity to corticosteroids, need for corticosteroids for other indication, active infections (e.g., tuberculosis, fungal infection, viral hepatitis), or do not intubate orders were excluded. Patients who were receiving steroids (for  $> 30$  days) at baseline or those who were pregnant or lactating were also excluded. Based on these criteria the study enrolled 143 participants (hydrocortisone group,  $n = 76$ ; placebo group,  $n = 73$ ) with a median age of 63.1 (IQR [interquartile range], 51.5 to 70.8) years and 66.3 years (IQR, 53.5 to 72.7) in the hydrocortisone group and placebo group respectively.

The Metcovid trial<sup>20</sup> enrolled adult patients ( $\geq 18$  years of age) with clinically or radiologically suspected COVID-19 who had an oxygen saturation ( $\text{SpO}_2$ )  $\leq 94\%$  in room air or were on supplementary oxygen or under mechanical ventilation. Clinical criteria included history of fever and any respiratory symptoms, and radiological criteria included ground glass opacity or pulmonary consolidation on computed tomography scan. Patients with known hypersensitivity to methylprednisolone, HIV/acquired immunodeficiency syndrome, chronic use of corticosteroids or immunosuppressants, decompensated cirrhosis, or chronic renal failure were excluded. Pregnant or lactating patients were also excluded. Based on these criteria the trial enrolled 393 participants (treatment group,  $n = 194$ ; placebo group,  $n = 199$ ) with a mean age of 54 years (standard deviation,  $\text{SD} = 15$ ) in each group.

The CoDEX trial<sup>21</sup> enrolled adult patients with acute respiratory distress syndrome (ARDS) who were admitted to the ICU due to confirmed or probable COVID-19. Exclusion criteria were pregnancy or active lactation, known hypersensitivity to dexamethasone, use of dexamethasone in the last 15 days (among non-hospitalized patients), other use of corticosteroids or immunosuppressive drugs, neutropenia, or imminent death. The trial enrolled 299 patients (dexamethasone group,  $n = 151$ ; control group,  $n = 148$ ) with a mean age of 61 years ( $\text{SD} = 14$ ).

Lastly, the REMAP-CAP trial<sup>22</sup> enrolled adult patients with presumed or confirmed SARS-CoV-2 infection with severe illness and admitted to the ICU for cardiovascular or respiratory organ support. Respiratory organ support was defined as either invasive or non-invasive mechanical ventilation or high-flow oxygen through nasal cannula with a flow rate  $\geq 30$  litres per minute or  $\text{FiO}_2 \geq 0.4$ . Cardiovascular organ support was defined as intravenous infusion of vasopressor or inotrope. Patients with hypersensitivity to hydrocortisone, systemic steroid use at baseline, ICU admission  $> 36$  hours prior to baseline, or those who were likely to be administered corticosteroids for reasons unrelated to COVID-19, or imminent death were excluded from the trial. The trial enrolled 403 patients (fixed-dose hydrocortisone,  $n = 137$ ; shock-dependent hydrocortisone,  $n = 146$ ; No hydrocortisone,  $n = 101$ ). The mean ages of the participants were 60.4 years ( $\text{SD} = 11.6$ ) in the fixed-dose hydrocortisone group, 59.5 years ( $\text{SD} = 12.7$ ) in the shock-dependent hydrocortisone group and 59.9 years ( $\text{SD} = 14.6$ ) in the no hydrocortisone group.

### *Interventions and Comparators*

The interventions of interest for the included SRs<sup>14-18</sup> were systemic corticosteroids for the management of COVID-19. Lu and colleagues<sup>14</sup> also specified that they considered a combination of glucocorticoids and symptomatic care as the intervention of interest. The comparator for all five SRs was non-administration of steroids (standard care).

In the CAPE-COVID trial,<sup>19</sup> the intervention was intravenous hydrocortisone with an initial dose of 200 mg/day as a continuous infusion. The treatment course was administered as 200 mg/day for the first 7 days, followed by 100 mg/day for 4 days, and 50 mg/day for 3 days (14 days in total). For patients whose general and respiratory status was improved by day 4, a shorter course was administered: 200 mg/day for the first 4 days, 100 mg for 2 days, and 50 mg/day for the next two days (8 days in total). Treatment with steroids was stopped for all patients on discharge from the ICU. The comparator was a placebo (saline solution).

In the Metcovid trial,<sup>20</sup> sodium succinate methyl prednisolone was administered at a dosage of 0.5 mg/kg twice daily for five days to patients in the treatment group. The comparator was a placebo (saline solution). All patients with ARDS were also administered antibiotics.

In the CoDEX trial,<sup>21</sup> 20 mg/day intravenous dexamethasone was administered for five days followed by 10 mg/day until discharge from the ICU, in addition to standard care. The comparator was standard care alone.

In the REMAP-CAP trial,<sup>22</sup> participants were divided into three groups based on the treatment they received. In the fixed-dose group, 50 mg intravenous hydrocortisone was given to patients every 6 hours for 7 days. In the shock-dependent group, patients received 50 mg intravenous hydrocortisone every 6 hours while in shock for up to 28 days. No hydrocortisone or other corticosteroids were given to those in the comparator group. It was noted that patients in all groups could receive steroids for non-COVID related indications such as bronchospasm, anaphylaxis or post-extubation stridor. By the end of the study 15% of patients in the no hydrocortisone group had received at least one dose of systemic steroids.

### *Outcomes*

The primary outcome for four of the SRs<sup>14,15,17,18</sup> was mortality, while the fifth SR<sup>16</sup> considered all health outcomes associated with corticosteroid treatment. Secondary outcomes that were considered in the SRs included duration of hospital stay,<sup>14,15,17</sup> duration of viral shedding,<sup>15,18</sup> duration of lung inflammation absorption,<sup>14</sup> duration of fever,<sup>14</sup> and ICU admission.<sup>18</sup> The definition of the outcome duration of lung inflammation absorption was unclear from the SR.<sup>14</sup> Adverse events were outcomes of interest in two SRs.<sup>14,17</sup> Follow-up duration in the included primary studies was not reported in any of the SRs.<sup>14-18</sup>

The primary outcome in the CAPE-COVID trial<sup>19</sup> was treatment failure on day 21, defined as death or continued dependency on mechanical ventilation or high-flow oxygen therapy. Secondary outcomes included proportion of patients with nosocomial infections and adverse events. Patients were followed for 21 days for all outcomes except nosocomial infection, for which follow-up was 28 days (post-hoc decision).

The primary outcome in the Metcovid trial<sup>20</sup> was 28-day mortality. The secondary outcomes included mortality at day 7 and 14, need for orotracheal intubation by day 7, and the proportion of patients with PaO<sub>2</sub>:FiO<sub>2</sub> ratio < 100 on day 7. The participants were followed for 28 days.

The primary outcome in the CoDEX trial<sup>21</sup> was 28-day ventilator-free days, defined as the number of days alive and not dependent on mechanical ventilation for a minimum of 48 consecutive hours. Patients who were discharged before 28 days were considered ventilator free at 28 days, whereas patients who died before 28 days were considered to have no ventilator free days. Secondary outcomes included 28-day all-cause mortality,

clinical status at day 15 (assessed using the 6-point disease severity scale by WHO, ranging from 1 [not hospitalized] to 6 [death]), ICU-free days, duration of mechanical ventilation, and organ failure assessed using sequential organ failure assessment (SOFA) scores. The SOFA scores range from 0 to 24, with a higher score indicating greater organ dysfunction. SOFA was assessed at 48 hours, 72 hours, and 7 days. Patients in the trial were followed for 28 days or until discharge, whichever came first.

The primary outcome in the REMAP-CAP trial<sup>22</sup> was respiratory and cardiovascular organ support-free days. Respiratory organ support was defined as either invasive or non-invasive mechanical ventilation or high-flow oxygen through nasal cannula with a flow rate  $\geq 30$  L/minute or  $\text{FiO}_2 \geq 0.4$ . Cardiovascular organ support was defined as intravenous infusion of vasopressor or inotrope. Secondary outcomes included time to death, duration of ICU stay, duration of hospital stay, cardiovascular organ support-free days, respiratory organ support-free days, and disease status at day 14 (assessed using the WHO ordinal scale ranging from 0 [no illness] to 8 [death]). Patients were followed for 21 days

## Summary of Critical Appraisal

Additional details regarding the strengths and limitations of included publications are provided in Appendix 3.

### *Systematic Reviews*

The five SR<sup>14-18</sup> authors described the objectives and inclusion criteria for the reviews, and included the components of population, intervention, comparators and outcomes of interest. Authors of one of the SRs reported that they had established their protocol prior to the conduct of the review.<sup>18</sup> The authors of all five SRs conducted comprehensive literature searches involving multiple electronic databases and detailed search strategies were reported.<sup>14-18</sup> Reference lists of selected articles were hand-searched for potential additional studies in three SRs.<sup>14,16,17</sup> In all reviews, study selection and data extraction from the selected studies were done independently by two reviewers, lowering risk of errors.<sup>14-18</sup> In four SRs, authors conducted quality assessments of the included primary studies using validated tools. Specifically, the Newcastle-Ottawa scale (three SRs),<sup>14,17,18</sup> Risk Of Bias In Non-randomized Studies of Interventions (ROBINS-I) (one SR)<sup>15</sup> for observational studies, and Cochrane risk of bias tool for RCTs (two SRs).<sup>14,15</sup> Four SRs<sup>14,15,17,18</sup> conducted meta-analyses to quantitatively synthesize results from the primary studies. Appropriate statistical techniques were used to conduct the meta-analyses, and heterogeneity was assessed using the  $I^2$  statistic in the four SRs.<sup>14,15,17,18</sup> Heterogeneity and risk of bias were considered while interpreting and discussing the results of the analyses in the four SRs.<sup>14,15,17,18</sup> The quality of the evidence was assessed using the Grading of Recommendations, Assessment, Development and Evaluations (GRADE) tool in two SRs.<sup>14,15</sup> The quality of the evidence from these SRs was reported as ranging from very low to low. Three of the SRs assessed publication bias using valid techniques, and showed publication bias was unlikely.<sup>14,15,17</sup>

As for the limitations, review methods and protocols were not registered a priori for two of the SRs due to time constraints.<sup>14,15</sup> It was unclear whether protocols were established a priori for two other SRs.<sup>16,17</sup> None of the included SRs provided a list of excluded studies or reasons for exclusion.<sup>14-18</sup> Three SRs<sup>14,15,18</sup> included non-peer-reviewed data from preprint publications. Because of the limitations of preprint publications (e.g., uncertain trustworthiness, findings may change from preprint to final published versions), including data from preprints lowered the internal validity of the analyses. One SR, in which data

were synthesized narratively (no meta-analysis), did not assess the risk of bias within the primary studies, which lowered the internal validity of the review.<sup>16</sup> In one SR, the definition of “duration of lung inflammation absorption” was not clearly defined.<sup>14</sup> In the SR by Sarkar and colleagues,<sup>15</sup> demographic characteristics (e.g., mean age, sex) of participants in primary studies were not reported. The meta-analyses of two SRs had high heterogeneity; however, the sources of heterogeneity were not discussed.<sup>14,15</sup> The author of one SR declared a conflict of interest as being an investigator in a trial evaluating the effect of corticosteroids in COVID-19, but it was unclear whether this was addressed and resolved.<sup>18</sup>

### *Randomized Controlled Trials*

The authors of four RCTs included in this report described their study objectives clearly and provided details regarding the inclusion criteria, interventions (dosage, administration and duration), comparators, and outcomes. The trial protocols were established and registered a priori and all of the trials used randomized allocation to assign participants to treatment groups.<sup>19-22</sup> Two studies were designed as double-blinded RCTs with allocation concealment.<sup>19,20</sup> Randomized allocation and blinding increased the internal validity of these studies. All trials reported detailed characteristics of patients for the overall sample.<sup>19-22</sup> Study findings were clearly described in the form of simple outcome data. Intention-to-treat analysis was conducted in two trials,<sup>20,21</sup> and in one RCT<sup>19</sup> missing outcome data were conservatively considered as treatment failure. Estimates of random variability were provided, such as confidence intervals, SDs, or IQRs.<sup>19-22</sup> Three RCTs<sup>19,21,22</sup> measured and reported important adverse events that may be a consequence of the intervention; however, adverse events in the comparator groups were also reported in only two of these trials.<sup>19,22</sup> All trials were conducted in centres where staff, places, and facilities were likely to be representative of the treatment the majority of patients receive. Two RCTs<sup>19,21,22</sup> were multicenter and one<sup>22</sup> was multinational and multicenter increasing the external generalizability of the results.

The main limitation of the RCTs was that three of the RCTs<sup>19,21,22</sup> were terminated early when preliminary results from the RECOVERY<sup>10</sup> trial (captured in this report through inclusion in a SR<sup>15</sup>) showed improved 28-day mortality with dexamethasone, leading researchers to determine it was not ethical to continue their trials. Accordingly, two RCTs<sup>19,22</sup> did not enrol enough study participants to ensure adequate statistical power. Since between-group statistical comparisons of participant baseline characteristics were not reported in two trials, it was unclear whether potential confounders were equally distributed between the groups.<sup>19,20</sup> The Metcovid trial did not report the incidence of adverse events in the intervention and control groups.<sup>20</sup> In the CoDEX trial,<sup>21</sup> the inclusion and exclusion criteria for study participation was changed after 182 patients had been enrolled, to better reflect the practical realities of treating COVID-19 patients in Brazil (e.g., the timing of admission to ICU was changed, as patients frequently receive an ARDS diagnosis and are placed on a ventilator prior to ICU admission due to ICU bed shortages in Brazil; patients were allowed to have been receiving corticosteroids at time of recruitment due to the widespread use of corticosteroids in hospitals in Brazil). It is possible that patients enrolled before and after the amendment were systematically different. However, the changes made to the protocol would be expected to bias the results toward the null if bias were introduced. The validity of, and minimal clinically important difference in the SOFA scores were not reported by the study authors.

The REMAP-CAP trial<sup>22</sup> had some additional methodological and reporting limitations. First, the analytical model assumed proportional effects across the primary outcome (organ support-free days). However, it was unclear whether this assumption was formally

assessed and met. Second, study participants were permitted to participate in multiple intervention domains within the broader trial and the primary analysis of the study included all participants. The analysis of relevance to this report (i.e., the comparison of participants treated with corticosteroids and those without) did not account for co-interventions, and these may have been imbalanced between intervention and comparison group. Thus, it was possible that the observed results were influenced by other interventions received by the patients. Third, it is difficult to interpret the clinical relevance of study findings due to the definition of the primary outcome. A composite variable labelled “respiratory and cardiovascular support-free days” included death as part of the composite (death labelled as -1, being the worst outcome). It is not clear why alternative approaches to analyzing these outcomes independently (e.g., a competing risk model) were not used. Fourth, the early termination of the study left the analysis underpowered. Lastly, fifteen percent of the patients in the control group (no hydrocortisone group) received systemic hydrocortisone for other indications, increasing the likelihood of bias toward smaller effect sizes.

For all RCTs, it was possible that participants in intervention and control groups received standard care and other concomitant medications and that the use of these medications affected the patient outcomes. Lastly, the authors of three RCTs<sup>19,21,22</sup> declared multiple conflicts of interests in the form of funding from pharmaceutical companies, grants and participation in other COVID-19 steroid trials. It was unclear whether these potentially relevant conflicts were addressed or resolved.

## Summary of Findings

### *Clinical Effectiveness of Systemic Corticosteroids*

#### **Mortality**

Mortality was examined in four SRs,<sup>14-16,18</sup> and three RCTs.<sup>19-21</sup>

The review authors reported inconsistent findings. Two meta-analyses showed higher mortality for patients treated with corticosteroids as compared to standard care (in a synthesis of twelve studies by Sarkar and colleagues,<sup>15</sup> and two studies in patients with severe illness by Ye and colleagues<sup>18</sup>). The between-group differences identified by Sarkar et al. were not significant in subgroup analyses for patients with mild illness, patients with critical illness, patients treated with low doses of corticosteroid, or patients treated with high doses of corticosteroid, potentially due to a lack of statistical power.<sup>15</sup> Similarly, Lu and colleagues reported no difference in the risk of mortality with systemic corticosteroids versus non-steroid treatment based on meta-analysis of data from five studies.<sup>14</sup> In contrast, patients with COVID-19 and ARDS who were treated with methyl prednisone had statistically significantly lower mortality than patients treated with usual care in one included primary study within the SR.<sup>18</sup>

Findings from narratively synthesized results were inconsistent as well. One observational study that was not included in the meta-analysis in the SR by Ye et al.<sup>18</sup> showed a significantly greater “mortality composite outcome or ICU admission” for patients with mixed severity COVID-19 who were treated with a corticosteroid versus those who were not. In contrast, authors of one observational study in patients with COVID-19 and ARDS that was included in the review by Veronese and colleagues<sup>16</sup> reported a statistically significantly lower risk of death in those treated with methyl prednisone versus usual care.

There were mixed favourable and null findings regarding mortality and the use of steroids in the included RCTs.<sup>20,21</sup> Three of the four RCTs showed null findings. Specifically, there

were no significant differences between low-dose hydrocortisone and placebo groups for treatment failure on day 21 (defined as death or continued dependency on mechanical ventilation or high-flow oxygen therapy) in the CAPE-COVID trial,<sup>19</sup> between methyl prednisone and placebo groups for mortality at 7-, 14-, or 28-days for the overall sample of patients in the Metcovid trial,<sup>20</sup> and steroid treatments (fixed-dose or shock-dependent hydrocortisone) were not superior to the non-steroid comparator in the REMAP-CAP trial for time to death.<sup>22</sup> However, post-hoc analysis of patients over 60 years of age in the Metcovid trial showed significantly lower 28-day mortality for those treated with methyl prednisone (46% mortality) versus placebo (61.9% mortality).<sup>20</sup> The CoDEX trial also produced favourable findings, where participants in the dexamethasone plus standard care treatment group had a mean of approximately 2.5 additional days alive and ventilator free than the standard care comparator group when examined at 28 days.<sup>21</sup>

### **Organ Support**

Randomized trials reported no difference between steroid and non-steroid groups for duration of mechanical ventilation (CoDEX trial), need for invasive mechanical ventilation until day seven (Metcovid trial),<sup>20</sup> or the proportion of patients with oxygenation index ( $\text{PaO}_2/\text{FiO}_2$ ) <100 until day seven (Metcovid trial).<sup>20</sup> Additionally, the REMAP-CAP trial demonstrated non-superiority of steroid intervention groups versus comparators for cardiovascular support-free days, organ support-free days, and respiratory support-free days.<sup>22</sup>

### **Sequential Organ Failure Assessment**

In the CoDEX trial, there was no difference between dexamethasone plus standard care versus standard care alone on adjusted SOFA scores for the prediction of mortality in COVID-19 patients when assessed at 48 hours, 72 hours, 7 days, or day 15.<sup>21</sup>

### **Pulmonary Fibrosis**

There was no difference between methyl prednisone and placebo groups for pulmonary fibrosis when assessed after day seven in the Metcovid trial.<sup>20</sup>

### **Bronchiolitis Obliterans with Organizing Pneumonia**

There was no difference between methyl prednisone and placebo groups for bronchiolitis obliterans with organizing pneumonia when assessed after day seven in the Metcovid trial.<sup>20</sup>

### **Duration of Fever**

One SR showed there were approximately three fewer days of fever in the corticosteroid group versus no corticosteroid in one included observational study of 46 people.<sup>14</sup>

### **Viral Shedding**

Viral shedding was examined in two SRs, which showed conflicting findings. Prolonged viral shedding with steroid use versus no steroid use was found in a meta-analysis of two observational studies,<sup>18</sup> while no significant difference between steroid and no steroid treatment was shown in a second meta-analysis of two observational studies.<sup>15</sup>

### **Presence of Viral RNA**

One study included in the SR by Veronese et al. examined the duration of viral RNA detection for oropharyngeal swabs and feces and showed duration in the corticosteroid

treatment group was longer than that in the non-corticosteroid treatment group.<sup>16</sup> In contrast, authors of the Metcovid trial reported that the presence of viral RNA in the naso/oropharyngeal swab did not differ between methyl prednisone or placebo groups on treatment day five or seven.<sup>20</sup>

### **Length of Hospital Stay or ICU Admission**

All four SRs<sup>14,15,17,18</sup> and three RCTs<sup>20-22</sup> examined hospitalization-related outcomes.

Authors of one study included in the SR by Veronese and colleagues examined ICU admissions, and observed that patients with COVID-19 and associated pneumonia who were treated with glucocorticoid therapy had a significantly greater percentage of ICU admissions compared to those who did not receive glucocorticoid therapy.<sup>16</sup>

Regarding length of hospital stay, there was no difference between steroid and non-steroid comparator groups in a meta-analysis of six trials.<sup>15</sup> In contrast, a meta-analysis of two observational studies showed that treatment with glucocorticoids was associated with approximately two more days in hospital than the non-steroid comparator.<sup>14</sup>

Authors of the RCTs showed there was no significant difference in hospitalization between corticosteroid intervention groups and non-corticosteroid comparison groups in the Metcovid and REMAP-CAP trials,<sup>20,22</sup> or ICU-free days in the CoDEX or REMAP-CAP trials.<sup>21,22</sup>

### **Lung Inflammation Absorption Time (Days)**

One SR showed no statistically significant difference between steroid and non-steroid groups with regard to lung inflammation absorption time.<sup>14</sup>

### **Adverse Events**

In the two SRs that examined adverse events, no adverse events were reported.<sup>14,17</sup>

Among the RCTs, nosocomial infections did not differ significantly between groups in the CAPE-COVID trial on day 28.<sup>19</sup> Authors of the CoDEX trial reported no significant differences between dexamethasone and standard care groups for serious adverse events, new diagnosis of infection by day 28, ventilator-associated pneumonia, catheter-related blood stream infection, catheter-associated urinary tract infections, bacteremia, insulin use for hyperglycemia, or “other” adverse effects.<sup>21</sup> Authors of the Metcovid trial reported no adverse events for either the steroid or intervention group.<sup>20</sup>

A list of single serious adverse events that were reported but not assessed statistically in the CAPE-COVID trial<sup>19</sup> and REMAP-CAP trial<sup>22</sup> can be found in Appendix 4 in a table of the main study findings and authors’ conclusions.

### **Limitations**

This report is not without limitations. The scientific world is still in the early stages of understanding the COVID-19 pandemic, and active research has been continuing to identify possible therapies for the disease. Although the current report identified five SRs and four RCTs evaluating the effectiveness of systemic corticosteroid therapy for COVID-19, there are several ongoing research trials. It is possible that the results from well-designed RCTs may be different from the findings of this report. The literature searches of four SRs<sup>14,16-18</sup> were conducted early in the pandemic, and captured records published up to April 2020, which precluded them from including any of the RCTs and observational

studies published later. The standard care and support given to participants in the early studies may be different from what a patient receives today, lowering the generalizability of the results to current Canadian settings. Patients who were pregnant or lactating were excluded from participating in included studies, further lowering the generalizability of the results. Three of the included RCTs<sup>19,21,22</sup> were terminated early and before recruiting the planned number of participants; two of the RCTs may have lacked adequate statistical power to detect significant differences between the groups.<sup>19,22</sup> Results from the included RCTs were from a follow-up period of 28 days or less. No evidence was found regarding the effectiveness and safety of corticosteroid therapy in the long term among patients with COVID-19. No evidence was found comparing the effectiveness of systemic corticosteroid therapy to other active treatments (e.g., remdesivir).

## Conclusions and Implications for Decision or Policy-Making

Five SRs<sup>14-18</sup> and four RCTs<sup>19-22</sup> were identified regarding the clinical effectiveness of systemic corticosteroids for the treatment of COVID-19.

Findings were inconsistent for mortality; compared to no corticosteroids or standard care, corticosteroids were associated with significantly less,<sup>16,20,21</sup> greater,<sup>15,18</sup> or no significant difference<sup>14,15,19,20,22</sup> in mortality.

There was no difference between treatment with steroids versus standard care or placebo for sequential organ failure assessment,<sup>21</sup> pulmonary fibrosis,<sup>20</sup> bronchiolitis obliterans with organizing pneumonia,<sup>20</sup> or lung inflammation absorption time.<sup>14</sup> A decrease in duration of fever was found with corticosteroids versus non-corticosteroid comparator in one SR.<sup>14</sup>

Contrasting findings suggesting prolonged-<sup>16</sup> or no difference<sup>20</sup> in viral shedding or presence of viral RNA detection in patients treated with corticosteroids compared to non-corticosteroid treatment in one included study in the SR by Veronese et al.,<sup>16</sup> and placebo in one RCT.<sup>20</sup>

Steroid treatment was associated with higher ICU admissions among patients with COVID-19 and pneumonia in one observational study included in one SR.<sup>16</sup> Two meta-analyses<sup>14,15</sup> showed longer duration- or no difference in duration of hospital stay between steroid and non-steroid comparators, while three RCTs<sup>20-22</sup> showed no difference between corticosteroid intervention and comparator (placebo)<sup>20</sup> or non-corticosteroid treatment<sup>21,22</sup> for duration of hospitalization or ICU-free days.

Adverse events were assessed in two of the five SRs, and neither SR reported any adverse events.<sup>14,17</sup> In the three RCTs that assessed adverse events, there were no significant differences between corticosteroid and non-corticosteroid comparator groups.<sup>19,21,22</sup>

The body of evidence included in this review consisted largely of research conducted early in the pandemic, with little follow-up (up to a maximum of 28 days). Therefore, the standard of care employed in the comparator groups is likely to differ from the care that is currently provided, and it is unknown whether any delayed-onset or enduring adverse events occurred.

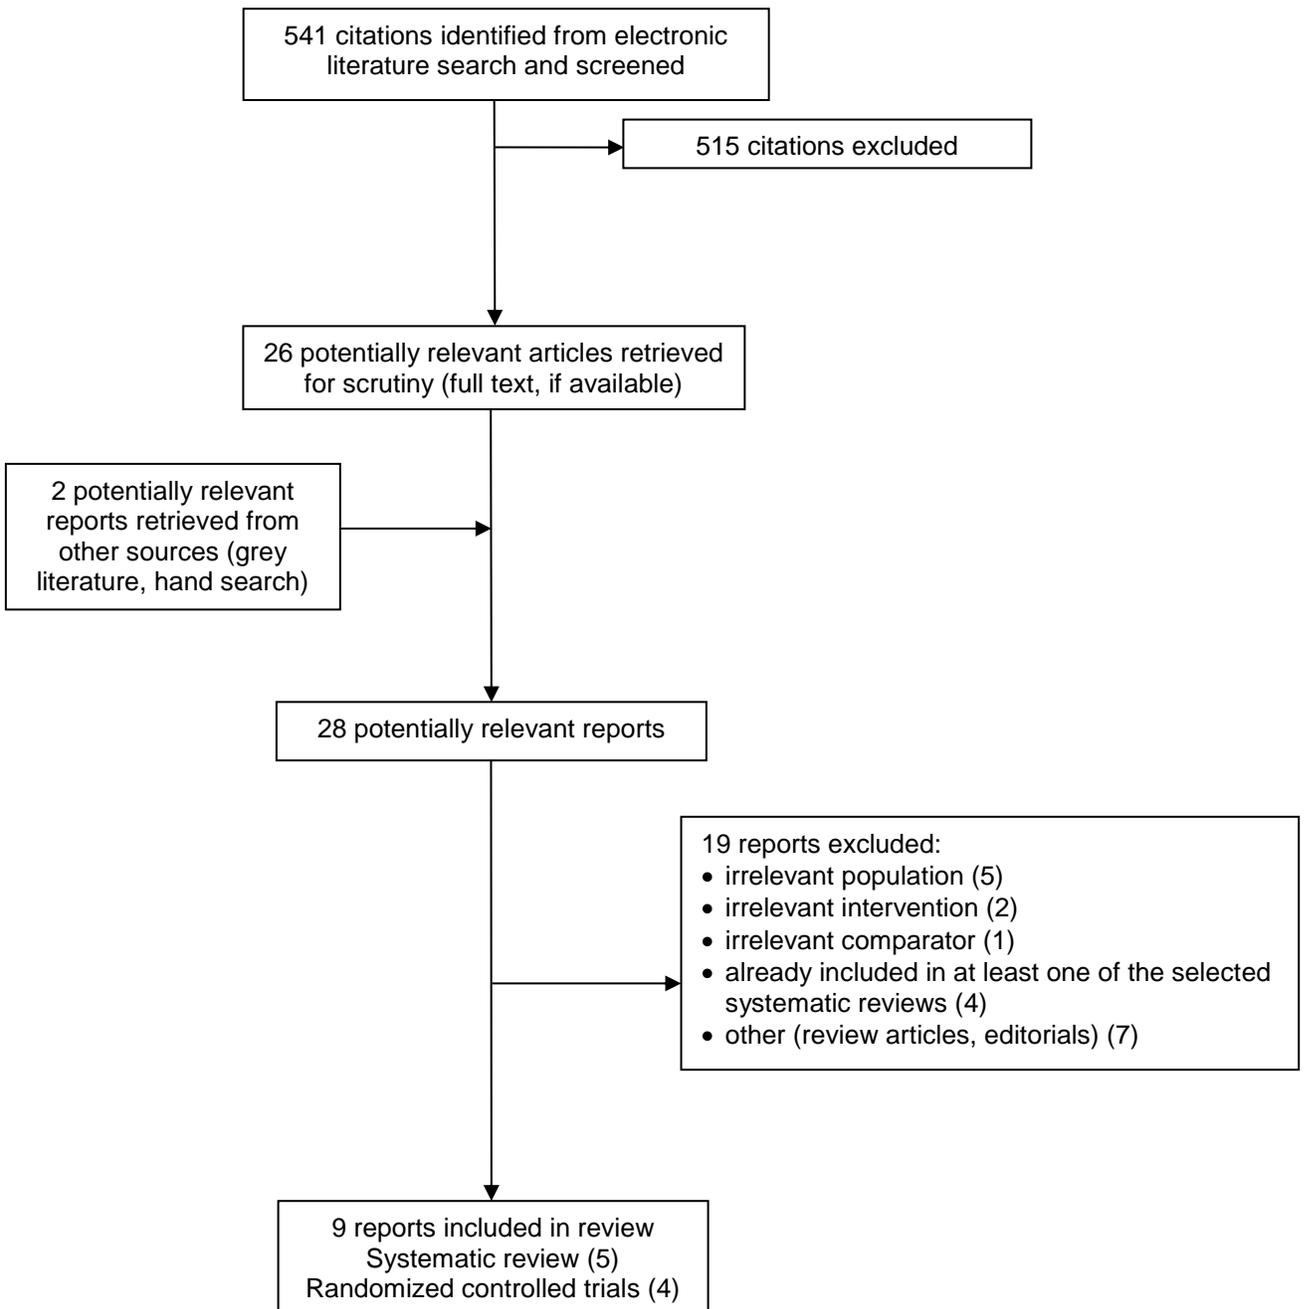

Further research addressing the effectiveness of systemic corticosteroids using well-designed RCTs with adequate sample sizes, longer duration of follow-up, and comparisons with other active drugs are needed to reduce uncertainty. Canada currently advises treatment with dexamethasone 6 mg intravenously for ten days or discharge (whichever is

earlier), or an equivalent glucocorticoid dose for patients who require supplemental oxygen or mechanical ventilation.<sup>1</sup> This advice is based on preliminary data from the RECOVERY trial (captured in the SR by Sarkar et al.<sup>15</sup>), which showed benefit in mortality at twenty-eight days for patients who required respiratory support at randomization and no benefit for those who did not.<sup>10</sup> Research that examines sub-groups of patients with COVID-19 and different stages of disease progression will provide clarity around existing guidance for the management of COVID-19 offered by the Public Health Agency of Canada and other jurisdictions.

## Appendix 3: Critical Appraisal of Included Publications

**Table 4: Strengths and Limitations of Systematic Reviews and Meta-Analyses using AMSTAR 2<sup>11</sup>**

Strengths	Limitations
<b>Lu et al., 2020<sup>14</sup></b>	
<ul style="list-style-type: none"> <li>• The objectives and inclusion criteria of the review were clearly reported and included components of population, intervention, comparators and outcome.</li> <li>• The authors conducted a comprehensive literature search involving multiple electronic databases. References of identified systematic reviews were searched for additional studies. A detailed search strategy was reported. Publication and language restrictions were reported and justified.</li> <li>• Study selection, data extraction and risk of bias assessment were conducted independently by two reviewers, lowering the risk of errors.</li> <li>• Characteristics of included studies were described in detail.</li> <li>• Valid tools were used to conduct risk of bias assessment of the included studies (Cochrane risk of bias for RCTs and Newcastle-Ottawa scale for cohort studies) and for the quality of evidence (GRADE).</li> <li>• A meta-analysis was performed using appropriate statistical techniques using random-effects model. Heterogeneity was assessed using I<sup>2</sup> statistic.</li> <li>• Predetermined subgroup analysis and sensitivity analysis was done.</li> <li>• Risk of bias assessments and heterogeneity were considered while interpreting evidence from meta-analyses.</li> <li>• Publication bias was assessed using Eggers test, which showed a bias was unlikely (P = 0.619).</li> <li>• The review authors had no significant conflicts of interest to declare.</li> </ul>	<ul style="list-style-type: none"> <li>• The review methods and protocol were not registered or published a priori.</li> <li>• Review authors did not explain their selection of the study designs for inclusion in the review.</li> <li>• Although the number of excluded studies were provided, reason for exclusion were not reported.</li> <li>• Non-peer-reviewed data from preprint publications were included in this study.</li> <li>• Definition of the outcome “duration of lung inflammation absorption” was unclear from the review.</li> <li>• The dosage and administration of corticosteroids in the relevant primary studies were not reported.</li> <li>• Sources of funding for the included primary studies were not reported.</li> <li>• It was unclear whether the sources of heterogeneity within the studies were investigated.</li> </ul>
<b>Sarkar et al., 2020<sup>15</sup></b>	
<ul style="list-style-type: none"> <li>• The objectives and inclusion criteria of the review were clearly reported and included components of population, intervention, comparators and outcome.</li> <li>• The authors conducted a comprehensive literature search involving multiple electronic databases. A detailed search strategy was reported. Publication and language restrictions were reported and justified.</li> <li>• Study selection, data extraction and risk of bias assessment were conducted independently by two reviewers, lowering the risk of errors.</li> <li>• Characteristics of included studies were described in detail.</li> <li>• Valid tools were used to conduct risk of bias assessment of the included studies (Cochrane risk of bias for RCTs and ROBINS-I for cohort studies) and the quality of evidence (GRADE).</li> <li>• A meta-analysis was performed using appropriate statistical techniques. Heterogeneity was assessed using I<sup>2</sup> statistic.</li> </ul>	<ul style="list-style-type: none"> <li>• The review methods and protocol were not registered and published a priori.</li> <li>• Review authors did not explain their selection of the study designs for inclusion in the review.</li> <li>• Although the number of excluded studies were provided, a list of excluded studies with reasons for exclusion were not provided.</li> <li>• Non-peer-reviewed data from preprint publications were included in this study.</li> <li>• Demographic characteristics (e.g., mean age, sex) and length of follow up of study participants from the included primary studies were not reported.</li> <li>• Sources of funding for the included primary studies were not reported.</li> <li>• The overall meta-analysis and subgroup analyses of the outcomes mortality and duration of hospital stay had high heterogeneity lowering the validity of the results. The sources of heterogeneity were not discussed.</li> </ul>

Strengths	Limitations
<ul style="list-style-type: none"> <li>• Risk of bias assessments and heterogeneity were considered while interpreting evidence from meta-analyses.</li> <li>• Publication bias was assessed using a Funnel plot, which showed a bias was unlikely.</li> <li>• The review authors had no significant conflicts of interest to declare.</li> </ul>	
<b>Veronese et al., 2020<sup>16</sup></b>	
<ul style="list-style-type: none"> <li>• The objectives and inclusion criteria of the review were clearly reported and included components of population, intervention, comparators and outcome.</li> <li>• The explanation for including randomized and non-randomized trials were reported.</li> <li>• The authors conducted a comprehensive literature search involving multiple electronic databases. Reference lists of identified studies were searched for additional studies. A detailed search strategy was reported. Handsearching of included studies and conference abstracts was done to identify additional studies.</li> <li>• Study selection and data extraction were conducted independently by two reviewers, lowering the risk for errors.</li> <li>• The number of excluded studies were provided and reasons for exclusion were reported.</li> <li>• The authors had no conflicts of interest to report.</li> </ul>	<ul style="list-style-type: none"> <li>• It was unclear whether the review methods and protocol were registered or published a priori.</li> <li>• Review authors did not explain their selection of the study designs for inclusion in the review.</li> <li>• The study designs of the included studies were unclear.</li> <li>• Quality assessment of the included studies was not done. Risk of bias from individual studies was not considered in the interpretation of results.</li> <li>• Publication bias was not assessed.</li> <li>• Funding sources of the systematic review and of the included studies were not reported.</li> </ul>
<b>Yang et al., 2020<sup>17</sup></b>	
<ul style="list-style-type: none"> <li>• The objectives and inclusion criteria of the review were clearly reported and included components of population, intervention, comparators and outcome.</li> <li>• The authors conducted a comprehensive literature search involving multiple electronic databases. References lists of identified studies were searched for additional studies. A detailed search strategy was reported. Handsearching of included studies was done to identify additional studies.</li> <li>• Study selection and data extraction were conducted independently by two reviewers, lowering the risk for errors.</li> <li>• Risk of bias of the included studies were assessed using Newcastle-Ottawa scale, which is a valid tool.</li> <li>• Characteristics of include studies such as study design, population, intervention, other treatments and outcomes were described.</li> <li>• A meta-analysis was performed using appropriate statistical techniques. Heterogeneity was assessed using I<sup>2</sup> statistic.</li> <li>• Risk of bias assessment and heterogeneity were considered while interpreting evidence from meta-analyses. Subgroup analyses was conducted to examine the sources of heterogeneity.</li> <li>• Publication bias was assessed using funnel plots. (although some publication bias was identified for the outcome mortality, it was not relevant to the current report, as no eligible data were reported).</li> <li>• The study authors reported conflicts of interest (there were none).</li> </ul>	<ul style="list-style-type: none"> <li>• It was unclear whether the review methods and protocol were registered and published a priori.</li> <li>• Review authors did not explain their selection of the study designs for inclusion in the review.</li> <li>• Study results from individual studies were not reported in the review.</li> <li>• Although the number of excluded studies was provided, a list of excluded studies with reasons for exclusion was not provided.</li> <li>• Funding sources of the included studies were not reported.</li> </ul>

Strengths	Limitations
<b>Ye et al., 2020<sup>18</sup></b>	
<ul style="list-style-type: none"> <li>• The objectives and inclusion criteria of the review were clearly reported and included components of population, intervention, comparators and outcome.</li> <li>• Review methods were established prior to the conduct of the review; however, authors did not report whether there were any deviations from the protocol.</li> <li>• The authors conducted a comprehensive literature search involving multiple electronic databases. References of identified studies were searched for additional studies. A detailed search strategy was reported.</li> <li>• Study selection, data extraction and risk of bias assessment were conducted independently by two reviewers, lowering the risk of errors.</li> <li>• Risk of bias in individual studies was assessed using the revised Newcastle-Ottawa scale.</li> <li>• Characteristics of included studies such as study design, population, intervention and outcomes were described.</li> <li>• Appropriate methods for statistical combination of results were used.</li> <li>• Review authors accounted for risk of bias in individual studies when interpreting the results of the review.</li> <li>• There was no significant heterogeneity.</li> </ul>	<ul style="list-style-type: none"> <li>• Review authors did not explain their selection of the study designs for inclusion in the review.</li> <li>• A list of potentially relevant studies that were read in full-text form but excluded from the review was not provided; exclusions for each study were not provided.</li> <li>• Study comparators were not described in adequate detail.</li> <li>• Review authors did not report the sources of funding for the studies included in the review.</li> <li>• Review authors reported a plan to investigate publication bias but it is not clear how or if this was done.</li> <li>• One author disclosed being an investigator on a trial evaluating the effect of corticosteroids in COVID-19 patients. However, the author did not explain how this potential important conflict of interest was resolved.</li> <li>• Non-peer-reviewed data from preprint publications were included in this study.</li> </ul>

COVID-19 = coronavirus disease 2019; GRADE = Grading of Recommendations, Assessment, Development and Evaluations; P = probability; RCT = randomized controlled trial; ROBINS-I = Risk Of Bias In Non-randomized Studies - of Interventions.

**Table 5: Strengths and Limitations of Clinical Studies using Downs and Black checklist<sup>12</sup>**

Strengths	Limitations
<b>Dequin et al., 2020<sup>19</sup></b>	
<ul style="list-style-type: none"> <li>• The study was designed as a double-blinded randomized study with randomized allocation and concealment of allocation.</li> <li>• The objectives of the study were clearly described. The inclusion criteria, intervention, comparators and outcomes were clearly described.</li> <li>• Characteristics of patients were clearly described, including inclusion and exclusion criteria.</li> <li>• Study findings were clearly described in the form of simple outcome data. Appropriate statistical tests were conducted to compare the groups. Estimates of random variability were provided such as confidence intervals and interquartile ranges. Actual probability values were reported for all outcomes.</li> <li>• Patients lost to follow up and withdrawn from the study were accounted for. For the primary outcome, missing data were conservatively considered treatment failure.</li> <li>• Study participants were representative of the population from which they were enrolled. Study participants of both groups were enrolled from same population over the same period of time. The staff, places and facilities for this multicenter study</li> </ul>	<ul style="list-style-type: none"> <li>• The study was discontinued early as per the decision of the DSMB. The study did not enroll enough participants to ensure adequate power as per the reported sample size estimation.</li> <li>• The baseline characteristics of study participants in the treatment and control group were not statistically compared. Thus, it was unclear if the potential confounders were equally distributed between the groups. Adequate adjustment for confounders in the analysis was not done.</li> <li>• The study authors declared several conflicts of interests (e.g., related to involvement with pharmaceutical companies). It was unclear whether these conflicts were relevant to the study.</li> </ul>

Strengths	Limitations
<p>were representative of the care majority of patients would receive.</p> <ul style="list-style-type: none"> <li>• Participants in both groups were followed up for the same duration.</li> <li>• A sample size calculation was done and reported based on the primary outcome.</li> <li>• Serious adverse events in both groups were reported. There were three events in the treatment group and no events in the control group.</li> </ul>	
<b>Jerónimo et al., 2020<sup>20</sup></b>	
<ul style="list-style-type: none"> <li>• The study was designed as a double-blinded randomized study with randomized allocation and concealment of allocation.</li> <li>• The objectives of the study were clearly described. The inclusion criteria, intervention, comparators and outcomes were clearly described.</li> <li>• Characteristics of patients were clearly described, including inclusion and exclusion criteria.</li> <li>• Study findings were clearly described in the form of simple outcome data. Appropriate statistical tests were conducted to compare the groups. Estimates of random variability were provided such as confidence intervals and interquartile ranges. Actual probability values were reported for all outcomes.</li> <li>• Patients lost to follow up and withdrawn from the study were accounted for. Modified intent-to-treat analysis and intent-to-treat analysis was conducted.</li> <li>• Study participants were representative of the population from which they were enrolled. The staff, places and facilities were representative of the care majority of patients would receive.</li> <li>• Participants in both groups were followed up for the same duration.</li> <li>• A sample size calculation was done and reported based on the primary outcome. The study enrolled enough participants to ensure adequate power.</li> <li>• The study authors described conflicts of interest (there were none).</li> </ul>	<ul style="list-style-type: none"> <li>• The baseline characteristics of study participants in the treatment and control group were not statistically compared. Thus, it was unclear if the potential confounders were equally distributed between the groups. Adequate adjustment for confounders in the analysis was not done.</li> <li>• Incidences of adverse events in treatment and control groups were not reported.</li> <li>• It is unknown if participants who were asked to participate in the study, or participants who prepared to participate in the study, were representative of the entire population from which they were recruited.</li> </ul>
<b>Tomazini et al., 2020<sup>21</sup></b>	
<ul style="list-style-type: none"> <li>• The objectives of the study were clearly described. The inclusion criteria, intervention, comparators and outcomes were clearly described.</li> <li>• Characteristics of patients were clearly described, including inclusion and exclusion criteria.</li> <li>• Study findings were clearly described in the form of simple outcome data. Appropriate statistical tests were conducted to compare the groups. Estimates of random variability were provided, such as confidence intervals and interquartile ranges. Actual probability values were reported for all outcomes.</li> <li>• All important adverse events that may be a consequence of the intervention were measured and reported.</li> <li>• There were no losses to follow-up or missing data.</li> </ul>	<ul style="list-style-type: none"> <li>• Inclusion and exclusion criteria were changed after 182 participants had been enrolled; timing of ARDS diagnosis changed from 24 to 48 hours; pre-enrolment administration of corticosteroids for one day during hospital stay was allowed. Use of immunosuppressive drugs, cytotoxic chemotherapy in the past 21 days, and neutropenia due to hematological or solid malignancies with bone marrow invasion were added to the exclusion list.</li> <li>• It was not possible to blind investigators, health care providers, or participants to group allocation during the trial due to the nature of the intervention.</li> <li>• 23 invited participants refused consent. It is not known if they differed from included participants.</li> <li>• Validity and reliability of outcome measures were not reported by study authors.</li> </ul>

Strengths	Limitations
<ul style="list-style-type: none"> <li>• Staff, places, and facilities where the patients were treated were representative of the treatment the majority of patients received.</li> <li>• Results were not based on data dredging.</li> <li>• The study was stopped early due to evidence of benefit from another study. However, it was adequately powered for main study outcomes.</li> <li>• Distributions of principal confounders in each group of subjects to be compared were clearly described. A list of principal confounders was provided.</li> <li>• Patients in different intervention groups were recruited from the same population and over the same period of time.</li> <li>• The randomized intervention assignment was generated by the trial statistician who was not involved in patient care or enrolment. Randomization sequence was concealed from patients and health care staff until enrolment was finalized.</li> <li>• Intention-to-treat analysis was used.</li> <li>• Protocol deviations in the control group were reported (i.e., 35% of patients in the control received corticosteroids during the study period) and authors suggested this may have been related to the open-label design, disease severity, or other differences. However, authors reported this would have biased results toward the null whereas a benefit of the intervention on the primary outcome was identified.</li> </ul>	<ul style="list-style-type: none"> <li>• It is unknown if participants asked to participate in the study or participants prepared to participate in the study were representative of the entire population from which they were recruited.</li> </ul>
<p><b>The Writing Committee for the REMAP-CAP Investigators, 2020<sup>22</sup></b></p>	
<ul style="list-style-type: none"> <li>• The objectives of the study were clearly described. The inclusion criteria, intervention, comparators and outcomes were clearly described.</li> <li>• Characteristics of patients were clearly described.</li> <li>• Study findings were clearly described in the form of simple outcome data. Appropriate statistical tests were conducted to compare the groups. The statistical analyses were done using Bayesian cumulative logistic model with a posterior distribution. Estimates of random variability was provided such as standard interval and interquartile ranges.</li> <li>• Any important adverse events that may be a consequence of the intervention were measured and reported.</li> <li>• The study enrolled participants from multiple study sites across countries, increasing the generalizability of the results.</li> <li>• Participants in both groups were followed up for the same duration.</li> </ul>	<ul style="list-style-type: none"> <li>• The baseline characteristics of study participants in the treatment and control group were not statistically compared. Thus, it was unclear if the potential confounders were equally distributed between the groups. Adequate adjustment for confounders in the analysis was not done.</li> <li>• Characteristics of patients lost to follow up were not described. It is possible they were different from those who continued in the study.</li> <li>• It is unknown if participants asked to participate in the study or participants prepared to participate in the study were representative of the entire population from which they were recruited.</li> <li>• The study was open label in design without blinding of participants or outcome assessors.</li> <li>• The trial was terminated early and did not enroll enough participants to ensure adequate power.</li> <li>• The reporting of study findings was challenging to interpret because of the way primary outcome was defined.</li> <li>• The analytical model assumed proportional effects across the primary outcome (ordinal organ support-free days). However, it was unclear whether this assumption was met.</li> <li>• Participants were permitted to participate in multiple intervention domains within the broader trial and the primary analysis of the study included all participants. The analysis of relevance to this report (i.e., the comparison of participants treated with corticosteroids and those without) did not account for co-interventions, and these may have been imbalanced between intervention and comparison groups.</li> </ul>

Strengths	Limitations
	<p>Thus, it was possible that the observed results were influenced by other interventions received by the patients.</p> <ul style="list-style-type: none"> <li>• Fifteen percent of the patients in the control group (no hydrocortisone group) received systemic hydrocortisone for other indications, increasing the likelihood of bias toward smaller effect sizes.</li> <li>• The study authors declared several conflicts of interests (e.g., involvement with pharmaceutical companies). It is unclear whether these conflicts were relevant to the study.</li> </ul>

ARDS = acute respiratory distress syndrome; DSMB = Data and Safety Monitoring Board.

## Appendix 4: Main Study Findings and Authors' Conclusions

**Table 6: Summary of Findings Included Systematic Reviews and Meta-Analyses**

Main Study Findings	Authors' Conclusion
<b>Lu et al., 2020<sup>14</sup></b>	
<p>Systematic review and meta-analysis of five cohort studies to summarize the evidence for the effectiveness and safety of glucocorticoid therapy in COVID-19 patients.</p> <p><b>Study findings</b>  <b>Risk of mortality</b>            Findings from five studies contributed to this analysis (n = 737)            Number of deaths/ total number of patients:            Steroid group: 94/329            Control group: 58/408            Steroid versus control, Risk Ratio (RR) (95% CI) = 2.00 (0.69 to 5.75)  <math>I^2 = 90.9\%</math>, <math>P = 0.000</math>            Quality of evidence: very low.</p> <p><b>Duration of fever, days</b>            Results from one study contributed to this analysis, (n = 46)            Steroid group, mean (SD) = 2.06 (0.28)            Control group, mean (SD) = 5.29 (0.7)            Weighted mean difference (95% CI) = -3.23 (-3.56 to -2.90)            Quality of evidence: very low.</p> <p><b>Lung inflammation absorption time, days</b>            Results from one study contributed to this analysis, (n = 72)            Steroid group, mean (SD) = 13 (3.1)            Control group, mean (SD) = 14 (4)            Weighted mean difference (95% CI) = -1.00 (-2.91 to 0.91)            Quality of evidence: very low.</p> <p><b>Length of hospital stay, days</b>            Results from two studies contributed to this analysis, (n = 365)            Steroid group, mean (SD) = NR            Control group, mean (SD) = NR            Weighted mean difference (95% CI) = 2.43 (1.42 to 3.43)  <math>I^2 = 0.0\%</math>; <math>P = 0.334</math>            Quality of evidence: very low.</p> <p>Adverse events in steroid group: NR            Adverse events in control group: NR</p>	<p>“In conclusion, glucocorticoid therapy may increase the risk of death in patients with coronavirus infections who have mild symptoms. We found no association between glucocorticoids and mortality in patients with severe symptoms. In the context of clinical trials, low-dose systemic glucocorticoid therapy for a short duration may be acceptable.” (p. 18)<sup>14</sup></p>
<b>Sarkar et al., 2020<sup>15</sup></b>	
<p>Systematic review and meta-analysis to summarize the evidence regarding the efficacy and safety of systemic steroid therapy in patients with COVID-19.</p> <p><b>Study findings:</b>  <b>Mortality</b>            Number of deaths/ total number of patients:            Findings from 12 trials contributed to this analysis            Corticosteroid: 1,306/5,611            No corticosteroid: 1,711/10,143</p>	<p>“In spite of some potential promising benefits, steroid therapy does not seem to reduce the risk of mortality, duration of hospital stays, and the period of viral shedding in COVID-19 patients. Further studies are necessary to substantiate the conclusive impact of steroids in COVID-19 patients.” (p. 8)<sup>15</sup></p>

Main Study Findings	Authors' Conclusion

<p>A systematic review and meta-analysis of to identify the roles of corticosteroid treatment in adult patients with SARS-CoV-2 infection.</p> <p>No relevant primary studies were included in the review.</p>	<p>“Patients with severe conditions were more likely to require corticosteroids. Corticosteroids could lead to higher mortality, longer LOS, a higher rate of bacterial infection and hypokalemia. Therefore, corticosteroid should be used with caution in the treatment of COVID-19 patients: corticosteroids are not recommended for patients with mild conditions, and moderate corticosteroids can be used in patients with severe conditions to suppress the immune response and reduce symptoms. Nevertheless, more multicenter clinical trials are needed to further verify this conclusion.” (p. e19)<sup>17</sup></p>

<b>The Writing Committee for the REMAP-CAP Investigators, 2020<sup>22</sup></b>	
<p>REMAP-CAP trial A multicenter open-label RCT to evaluate the effect of intravenous hydrocortisone in patients with severe COVID-19.</p> <p>Total number of participants, N = 403 Fixed-dose HC, n = 137 Shock-dependent HC, n = 146 No HC group, n = 101</p> <p><b>Study findings:</b></p> <ul style="list-style-type: none"> <li>● <b>Organ support-free days:</b> <ul style="list-style-type: none"> <li>○ Fixed-dose HC, median (IQR) = 0 (-1 to 15)</li> <li>○ Shock-dependent HC, median (IQR) = 0 (-1 to 13)</li> <li>○ No HC, median (IQR) = 0 (-1 to 11)</li> </ul> </li> </ul>	<p>“Among patients with severe COVID-19, treatment with a 7-day fixed-dose course of hydrocortisone or shock-dependent dosing of hydrocortisone, compared with no hydrocortisone, resulted in 93% and 80% probabilities of superiority with regard to the odds of improvement in organ support–free days within 21 days. However, the trial was stopped early and no treatment strategy met prespecified criteria for statistical superiority, precluding definitive conclusions.” (p. E11)<sup>22</sup></p>

Main Study Findings	Authors' Conclusion
